

Machine Learning

Regularization

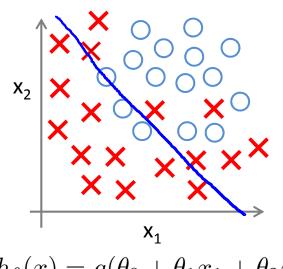

The problem of overfitting

Example: Linear regression (housing prices)

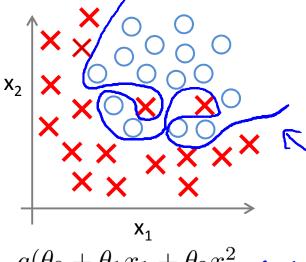

Overfitting: If we have too many features, the learned hypothesis may fit the training set very well $(J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 \approx 0)$, but fail to generalize to new examples (predict prices on new examples).

Example: Logistic regression

$$X_2$$
 X_2
 X_3
 X_4
 X_4

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$$

$$(g = \text{sigmoid function})$$

$$(g = \text{sigmoid function})$$

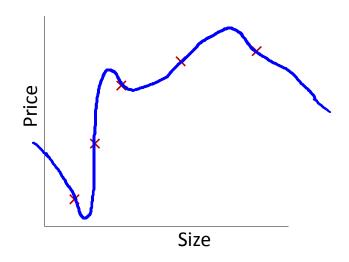

$$g(\theta_{0} + \theta_{1}x_{1} + \theta_{2}x_{2} + \theta_{3}x_{1}^{2} + \theta_{4}x_{2}^{2} + \theta_{5}x_{1}x_{2})$$

$$g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \theta_6 x_1^3 x_2 + \dots)$$

Addressing overfitting:

 x_{100}

```
x_1= size of house x_2= no. of bedrooms x_3= no. of floors x_4= age of house x_5= average income in neighborhood x_6= kitchen size
```

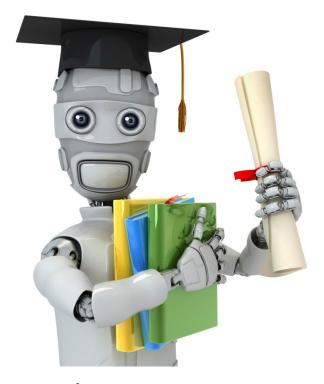

Underfitting, or high bias, is when the form of our hypothesis function h maps poorly to the trend of the data, It is usually caused by a function that is too simple or uses too few features.

overfitting, or high variance, is caused by a hypothesis function that fits the available data but does not generalize well to predict new data. It is usually caused by a complicated function that creates a lot of unnecessary curves and angles unrelated to the data.

Addressing overfitting:

Options:

- 1. Reduce number of features.
- Manually select which features to keep.
- —> Model selection algorithm (later in course).
- 2. Regularization.
 - \rightarrow Keep all the features, but reduce magnitude/values of parameters θ_{i} .
 - Works well when we have a lot of features, each of which contributes a bit to predicting y.

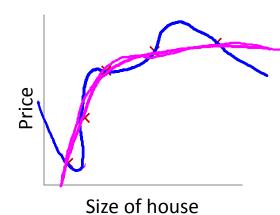

Machine Learning

Regularization

Cost function

Intuition

$$\theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

Suppose we penalize and make θ_3 , θ_4 really small.

Regularization. Lamda: It determines how much the costs of our theta parameters are inflated if lambda is chosen to be too large, it may smooth out the function too much and cause underfitting

علشان ال i = 2 او

Small values for parameters $\theta_0, \theta_1, \dots, \theta_n$

- "Simpler" hypothesis
- Less prone to overfitting <

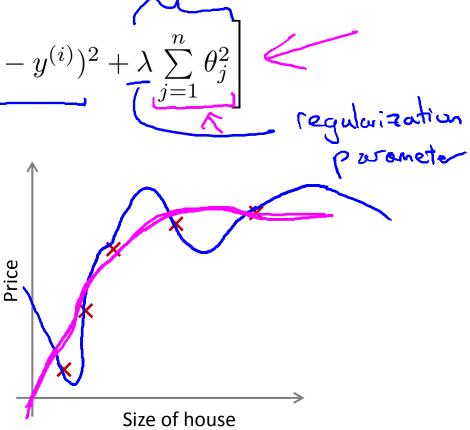

Housing:

- Features: $\underline{x}_1, x_2, \dots, x_{100}$
- Parameters: $\theta_0, \theta_1, \theta_2, \dots, \theta_{100}$

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \sum_{i$$

Regularization term to shrink all parameters to smaller values

Regularization.

In regularized linear regression, we choose θ to minimize

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^{n} \theta_j^2 \right]$$

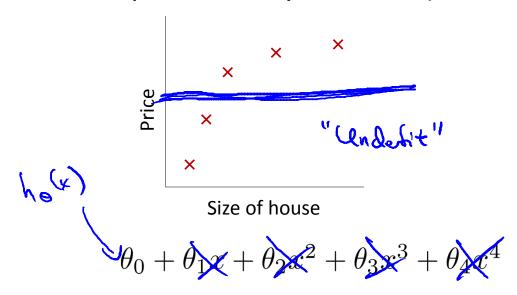

What if λ is set to an extremely large value (perhaps for too large for our problem, say $\lambda=10^{10}$)?

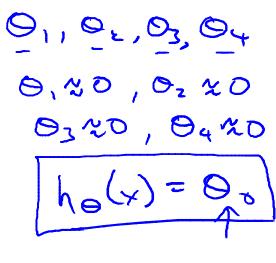

- Algorithm works fine; setting λ to be very large can't hurt it
- Algortihm fails to eliminate overfitting.
- Algorithm results in underfitting. (Fails to fit even training data well).
- Gradient descent will fail to converge.

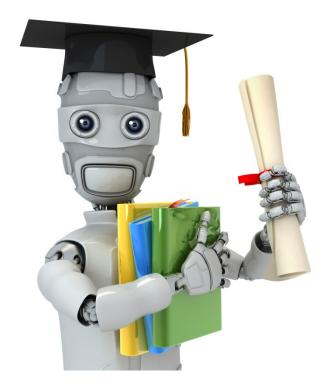

In regularized linear regression, we choose θ to minimize

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \underbrace{\lambda}_{j=1}^{n} \theta_j^2 \right]$$

What if λ is set to an extremely large value (perhaps for too large for our problem, say $\lambda=10^{10}$)?

Machine Learning

Regularization

Regularized linear regression

Regularized linear regression

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \left(\sum_{j=1}^{n} \theta_j^2 \right) \right]$$

$$\min_{\theta} J(\theta)$$

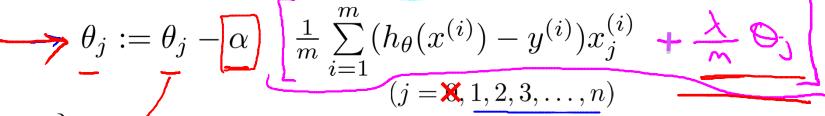

Gradient descent

$$\bigcirc$$
, \bigcirc , \bigcirc , \bigcirc n

$$\theta_0 := \theta_0 - \alpha \frac{1}{m}$$

$$\alpha \frac{1}{m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)}) x_0^{(i)}$$

$$\theta_{j} := \theta_{j} (1 - \alpha \frac{\lambda}{m})$$

$$\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)}) x_{j}^{(i)}$$

Normal equation

$$X = \begin{bmatrix} (x^{(1)})^T \\ \vdots \\ (x^{(m)})^T \end{bmatrix}$$

$$\Rightarrow \min_{\theta} J(\theta)$$

$$\Rightarrow 0 = (x^T \times + \lambda) \begin{bmatrix} y^{(1)} \\ \vdots \\ y^{(m)} \end{bmatrix}$$

$$\Rightarrow \sum_{\theta \in \mathcal{I}} J(\theta)$$

$$\Rightarrow \sum_{\theta \in \mathcal{I}} J(\theta) = \sum_{\theta \in \mathcal{I}} J(\theta)$$

Non-invertibility (optional/advanced).

Suppose
$$m \le n$$
, (#examples) (#features)

$$\theta = \underbrace{(X^T X)^{-1} X^T y}_{\text{Non-invertible / Singular}}$$

If
$$\frac{\lambda > 0}{\theta} = \left(X^T X + \lambda \begin{bmatrix} 0 & 1 & 1 & 1 \\ & 1 & & \\ & & \ddots & 1 \end{bmatrix} \right)^{-1} X^T y$$
